Package 'cTMed'

| January 11, 2025 |
|---|
| Title Continuous Time Mediation |
| Version 1.0.4.9000 |
| Description Calculates standard errors and confidence intervals for effects in continuous-time mediation models. This package extends the work of Deboeck and Preacher (2015) <doi:10.1080 10705511.2014.973960=""> and Ryan and Hamaker (2021) <doi:10.1007 s11336-021-09767-0=""> by providing methods to generate standard errors and confidence intervals for the total, direct, and indirect effects in these models.</doi:10.1007></doi:10.1080> |

| | | | | | | |
| Index | | | | | | 140 |
| Boot | Beta | Lag | • | 1 0 | v | Elements of the Matrix of sterval or a Range of Time |

Description

This function generates a bootstrap method sampling distribution for the elements of the matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix Φ .

Usage

```
BootBeta(phi, phi_hat, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a bootstrap estimate of the drift matrix (Φ) . |
|---------|---|
| phi_hat | Numeric matrix. The estimated drift matrix $(\hat{\Phi})$ from the original data set. phi_hat should have row and column names pertaining to the variables in the system. |
| delta_t | Numeric. Time interval (Δt). |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See Total().

Value

Returns an object of class ctmedboot which is a list with the following elements:

```
call Function call.args Function arguments.fun Function used ("BootBeta").output A list with length of length(delta_t).
```

4 BootBeta

Each element in the output list has the following elements:

est Estimated elements of the matrix of lagged coefficients.

thetahatstar A matrix of bootstrap elements of the matrix of lagged coefficients.

BootBetaStd

Bootstrap Sampling Distribution for the Elements of the Standardized Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a bootstrap method sampling distribution for the elements of the standardized matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix Φ .

Usage

```
BootBetaStd(phi, sigma, phi_hat, sigma_hat, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a bootstrap estimate of the drift matrix (Φ) . |
|-----------|---|
| sigma | List of numeric matrices. Each element of the list is a bootstrap estimate of the process noise covariance matrix (Σ) . |
| phi_hat | Numeric matrix. The estimated drift matrix $(\hat{\Phi})$ from the original data set. phi_hat should have row and column names pertaining to the variables in the system. |
| sigma_hat | Numeric matrix. The estimated process noise covariance matrix $(\hat{\Sigma})$ from the original data set. |
| delta_t | Numeric. Time interval (Δt) . |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd().

Value

Returns an object of class ctmedboot which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("BootBetaStd").

output A list with length of length(delta_t).

Each element in the output list has the following elements:

est Estimated elements of the standardized matrix of lagged coefficients.

thetahatstar A matrix of bootstrap elements of the standardized matrix of lagged coefficients.

BootMed

Bootstrap Sampling Distribution of Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a bootstrap method sampling distribution of the total, direct and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix $\mathbf{\Phi}$.

Usage

```
BootMed(phi, phi_hat, delta_t, from, to, med, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a bootstrap estimate of the drift matrix (Φ) . |
|----------|---|
| phi_hat | Numeric matrix. The estimated drift matrix $(\hat{\Phi})$ from the original data set. phi_hat should have row and column names pertaining to the variables in the system. |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| 11001 00 | |

Details

tol

See Total(), Direct(), and Indirect() for more details.

Value

Returns an object of class ctmedboot which is a list with the following elements:

Numeric. Smallest possible time interval to allow.

```
call Function call.
```

args Function arguments.

fun Function used ("BootMed").

output A list with length of length(delta_t).

Each element in the output list has the following elements:

est A vector of total, direct, and indirect effects.

thetahatstar A matrix of bootstrap total, direct, and indirect effects.

BootMedStd

Bootstrap Sampling Distribution of Standardized Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a bootstrap method sampling distribution of the standardized total, direct and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix $\mathbf{\Phi}$.

Usage

```
BootMedStd(
   phi,
   sigma,
   phi_hat,
   sigma_hat,
   delta_t,
   from,
   to,
   med,
   ncores = NULL,
   tol = 0.01
)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a bootstrap estimate of the drift matrix (Φ) . |
|-----------|---|
| sigma | List of numeric matrices. Each element of the list is a bootstrap estimate of the process noise covariance matrix (Σ) . |
| phi_hat | Numeric matrix. The estimated drift matrix $(\hat{\Phi})$ from the original data set. phi_hat should have row and column names pertaining to the variables in the system. |
| sigma_hat | Numeric matrix. The estimated process noise covariance matrix $(\hat{\Sigma})$ from the original data set. |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd(), DirectStd(), and IndirectStd() for more details.

Value

Returns an object of class ctmedboot which is a list with the following elements:

```
call Function call.
args Function arguments.
fun Function used ("BootMedStd").
output A list with length of length(delta_t).
```

Each element in the output list has the following elements:

est A vector of standardized total, direct, and indirect effects.

thetahatstar A matrix of bootstrap standardized total, direct, and indirect effects.

Description

Bootstrap Method Confidence Intervals

Usage

```
## S3 method for class 'ctmedboot'
confint(object, parm = NULL, level = 0.95, type = "pc", ...)
```

Arguments

object Object of class ctmedboot.

parm a specification of which parameters are to be given confidence intervals, either

a vector of numbers or a vector of names. If missing, all parameters are consid-

ered.

level the confidence level required.

type Charater string. Confidence interval type, that is, type = "pc" for percentile;

type = "bc" for bias corrected.

... additional arguments.

Value

Returns a data frame of confidence intervals.

DeltaBeta

Delta Method Sampling Variance-Covariance Matrix for the Elements of the Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the elements of the matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix Φ .

Usage

```
DeltaBeta(phi, vcov_phi_vec, delta_t, ncores = NULL, tol = 0.01)
```

26 DeltaBeta

Arguments

phi Numeric matrix. The drift matrix (Φ) , phi should have row and column names

pertaining to the variables in the system.

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$.

delta_t Vector of positive numbers. Time interval (Δt).

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when the length of delta_t is long.

tol Numeric. Smallest possible time interval to allow.

Details

See Total().

Delta Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. By the multivariate central limit theory, the function g using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\mathbf{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), \mathbf{J}\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right) \mathbf{J}'\right).$$

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaBeta").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

DeltaBeta 27

jacobian Jacobian matrix.

est Estimated elements of the matrix of lagged coefficients.

vcov Sampling variance-covariance matrix of estimated elements of the matrix of lagged coefficients.

DeltaBetaStd

Delta Method Sampling Variance-Covariance Matrix for the Elements of the Standardized Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the elements of the standardized matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix Φ and process noise covariance matrix Σ .

Usage

DeltaBetaStd(phi, sigma, vcov_theta, delta_t, ncores = NULL, tol = 0.01)

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
|------------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| vcov_theta | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\mathbf{\Phi}\right)$ and $\operatorname{vech}\left(\mathbf{\Sigma}\right)$ |
| delta_t | Numeric. Time interval (Δt). |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd().

Delta Method:

Let θ be a vector that combines $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise and $\operatorname{vech}(\Sigma)$, that is, the unique elements of the Σ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be a vector that combines $\operatorname{vec}(\hat{\Phi})$ and $\operatorname{vech}(\hat{\Sigma})$. By the multivariate central limit theory, the function \mathbf{g} using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $g(\hat{\theta})$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\mathbf{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{oldsymbol{ heta}}
ight)pprox\mathcal{N}\left(\mathbf{g}\left(oldsymbol{ heta}
ight),\mathbf{J}\hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)\mathbf{J}'
ight).$$

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaBetaStd").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

jacobian Jacobian matrix.

est Estimated elements of the standardized matrix of lagged coefficients.

vcov Sampling variance-covariance matrix of estimated elements of the standardized matrix of lagged coefficients.

DeltaIndirectCentral Delta Method Sampling Variance-Covariance Matrix for the Indirect

Effect Centrality Over a Specific Time Interval or a Range of Time

Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the indirect effect centrality over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix Φ .

Usage

```
DeltaIndirectCentral(phi, vcov_phi_vec, delta_t, ncores = NULL, tol = 0.01)
```

DeltaIndirectCentral 33

Arguments

phi Numeric matrix. The drift matrix (Φ) , phi should have row and column names

pertaining to the variables in the system.

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$.

delta_t Vector of positive numbers. Time interval (Δt).

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when the length of delta_t is long.

tol Numeric. Smallest possible time interval to allow.

Details

See IndirectCentral() more details.

Delta Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. By the multivariate central limit theory, the function g using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), \mathbf{J}\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right) \mathbf{J}'\right).$$

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaIndirectCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

34 DeltaIndirectCentral

jacobian Jacobian matrix.

est Estimated indirect effect centrality.

vcov Sampling variance-covariance matrix of estimated indirect effect centrality.

DeltaMed

Delta Method Sampling Variance-Covariance Matrix for the Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the total, direct, and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$.

Usage

DeltaMed(phi, vcov_phi_vec, delta_t, from, to, med, ncores = NULL, tol = 0.01)

Arguments

phi Numeric matrix. The drift matrix (Φ), phi should have row and column names pertaining to the variables in the system.

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of $vec(\Phi)$.

delta_t Vector of positive numbers. Time interval (Δt).

from Character string. Name of the independent variable X in phi. to Character string. Name of the dependent variable Y in phi. med Character vector. Name/s of the mediator variable/s in phi.

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when the length of delta_t is long.

tol Numeric. Smallest possible time interval to allow.

Details

See Total(), Direct(), and Indirect() for more details.

Delta Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. By the multivariate central limit theory, the function \mathbf{g} using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{oldsymbol{ heta}}
ight)pprox\mathcal{N}\left(\mathbf{g}\left(oldsymbol{ heta}
ight),\mathbf{J}\hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)\mathbf{J}'
ight).$$

DeltaMed 37

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaMed").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

jacobian Jacobian matrix.

est Estimated total, direct, and indirect effects.

vcov Sampling variance-covariance matrix of the estimated total, direct, and indirect effects.

DeltaMedStd

Delta Method Sampling Variance-Covariance Matrix for the Standardized Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the standardized total, direct, and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$ and process noise covariance matrix $\mathbf{\Sigma}$.

Usage

```
DeltaMedStd(
   phi,
   sigma,
   vcov_theta,
   delta_t,
   from,
   to,
   med,
   ncores = NULL,
   tol = 0.01
)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) , phi should have row and column names pertaining to the variables in the system. |
|----------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| vcov_the | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\mathbf{\Phi}\right)$ and $\operatorname{vech}\left(\mathbf{\Sigma}\right)$ |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |

| to | Character string. Name of the dependent variable Y in phi. | |
|--------|--|--|
| med | Character vector. Name/s of the mediator variable/s in phi. | |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. | |
| tol | Numeric Smallest possible time interval to allow | |

Details

See TotalStd(), DirectStd(), and IndirectStd() for more details.

Delta Method:

Let θ be a vector that combines $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise and $\operatorname{vech}(\Sigma)$, that is, the unique elements of the Σ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be a vector that combines $\operatorname{vec}(\hat{\Phi})$ and $\operatorname{vech}(\hat{\Sigma})$. By the multivariate central limit theory, the function \mathbf{g} using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), \mathbf{J}\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right) \mathbf{J}'\right).$$

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaMedStd").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

jacobian Jacobian matrix.

est Estimated standardized total, direct, and indirect effects.

vcov Sampling variance-covariance matrix of the estimated standardized total, direct, and indirect effects.

DeltaTotalCentral

Delta Method Sampling Variance-Covariance Matrix for the Total Effect Centrality Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the delta method sampling variance-covariance matrix for the total effect centrality over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix Φ .

Usage

```
DeltaTotalCentral(phi, vcov_phi_vec, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
|--------------|--|
| vcov_phi_vec | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$. |
| delta_t | Vector of positive numbers. Time interval (Δt). |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when the length of delta_t is long. |
| tol | Numeric. Smallest possible time interval to allow. |

44 DeltaTotalCentral

Details

See TotalCentral() more details.

Delta Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. By the multivariate central limit theory, the function \mathbf{g} using $\hat{\theta}$ as input can be expressed as:

$$\sqrt{n}\left(\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) - \mathbf{g}\left(\boldsymbol{\theta}\right)\right) \xrightarrow{\mathrm{D}} \mathcal{N}\left(0, \mathbf{J}\boldsymbol{\Gamma}\mathbf{J}'\right)$$

where **J** is the matrix of first-order derivatives of the function **g** with respect to the elements of θ and Γ is the asymptotic variance-covariance matrix of $\hat{\theta}$.

From the former, we can derive the distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ as follows:

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), n^{-1}\mathbf{J}\mathbf{\Gamma}\mathbf{J}'\right)$$

The uncertainty associated with the estimator $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is, therefore, given by $n^{-1}\mathbf{J}\Gamma\mathbf{J}'$. When Γ is unknown, by substitution, we can use the estimated sampling variance-covariance matrix of $\hat{\boldsymbol{\theta}}$, that is, $\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)$ for $n^{-1}\Gamma$. Therefore, the sampling variance-covariance matrix of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ is given by

$$\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right) \approx \mathcal{N}\left(\mathbf{g}\left(\boldsymbol{\theta}\right), \mathbf{J}\hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right) \mathbf{J}'\right).$$

Value

Returns an object of class ctmeddelta which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("DeltaTotalCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

delta_t Time interval.

jacobian Jacobian matrix.

est Estimated total effect centrality.

vcov Sampling variance-covariance matrix of estimated total effect centrality.

Direct

Direct Effect of X on Y Over a Specific Time Interval

Description

This function computes the direct effect of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$.

Usage

```
Direct(phi, delta_t, from, to, med)
```

Direct 47

Arguments

| pertaining to the variables in the system. delta_t Numeric. Time interval (Δt) . from Character string. Name of the independent variable X in phi. to Character string. Name of the dependent variable Y in phi. med Character vector. Name/s of the mediator variable/s in phi. | phi | Numeric matrix. The drift matrix (Φ). phi should have row and column names |
|--|---------|---|
| from Character string. Name of the independent variable X in phi. to Character string. Name of the dependent variable Y in phi. | | pertaining to the variables in the system. |
| to Character string. Name of the dependent variable Y in phi. | delta_t | Numeric. Time interval (Δt). |
| | from | Character string. Name of the independent variable X in phi. |
| med Character vector. Name/s of the mediator variable/s in phi. | to | Character string. Name of the dependent variable Y in phi. |
| | med | Character vector. Name/s of the mediator variable/s in phi. |

Details

The direct effect of the independent variable X on the dependent variable Y relative to some mediator variables \mathbf{m} is given by

$$\operatorname{Direct}_{\Delta t_{i,j}} = \exp\left(\Delta t \mathbf{D} \mathbf{\Phi} \mathbf{D}\right)_{i,j}$$

where Φ denotes the drift matrix, \mathbf{D} a diagonal matrix where the diagonal elements corresponding to mediator variables \mathbf{m} are set to zero and the rest to one, i the row index of Y in Φ , j the column index of X in Φ , and Δt the time interval.

Linear Stochastic Differential Equation Model:

The measurement model is given by

$$\mathbf{y}_{i,t} = \boldsymbol{\nu} + \boldsymbol{\Lambda} \boldsymbol{\eta}_{i,t} + \boldsymbol{\varepsilon}_{i,t}, \quad ext{with} \quad \boldsymbol{\varepsilon}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \boldsymbol{\Theta}\right)$$

where $\mathbf{y}_{i,t}$, $\boldsymbol{\eta}_{i,t}$, and $\boldsymbol{\varepsilon}_{i,t}$ are random variables and $\boldsymbol{\nu}$, $\boldsymbol{\Lambda}$, and $\boldsymbol{\Theta}$ are model parameters. $\mathbf{y}_{i,t}$ represents a vector of observed random variables, $\boldsymbol{\eta}_{i,t}$ a vector of latent random variables, and $\boldsymbol{\varepsilon}_{i,t}$ a vector of random measurement errors, at time t and individual i. $\boldsymbol{\nu}$ denotes a vector of intercepts, $\boldsymbol{\Lambda}$ a matrix of factor loadings, and $\boldsymbol{\Theta}$ the covariance matrix of $\boldsymbol{\varepsilon}$.

An alternative representation of the measurement error is given by

$$oldsymbol{arepsilon}_{i,t} = oldsymbol{\Theta}^{rac{1}{2}} \mathbf{z}_{i,t}, \quad ext{with} \quad \mathbf{z}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{I}\right)$$

where $\mathbf{z}_{i,t}$ is a vector of independent standard normal random variables and $\left(\Theta^{\frac{1}{2}}\right)\left(\Theta^{\frac{1}{2}}\right)' = \Theta$. The dynamic structure is given by

$$\mathrm{d} \boldsymbol{\eta}_{i,t} = \left(\boldsymbol{\iota} + \boldsymbol{\Phi} \boldsymbol{\eta}_{i,t} \right) \mathrm{d} t + \boldsymbol{\Sigma}^{\frac{1}{2}} \mathrm{d} \mathbf{W}_{i,t}$$

where ι is a term which is unobserved and constant over time, Φ is the drift matrix which represents the rate of change of the solution in the absence of any random fluctuations, Σ is the matrix of volatility or randomness in the process, and $\mathrm{d}W$ is a Wiener process or Brownian motion, which represents random fluctuations.

Value

Returns an object of class ctmedeffect which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("Direct").

output The direct effect.

48 Direct

DirectStd

Standardized Direct Effect of X on Y Over a Specific Time Interval

Description

This function computes the standardized direct effect of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$ and process noise covariance matrix $\mathbf{\Sigma}$.

Usage

```
DirectStd(phi, sigma, delta_t, from, to, med)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) , phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |

Details

The standardized direct effect of the independent variable X on the dependent variable Y relative to some mediator variables \mathbf{m} is given by

$$\operatorname{Direct}_{\Delta t_{i,j}}^{*} = \mathbf{S}\left(\exp\left(\Delta t \mathbf{D} \mathbf{\Phi} \mathbf{D}\right)_{i,j}\right) \mathbf{S}^{-1}$$

where Φ denotes the drift matrix, \mathbf{D} a diagonal matrix where the diagonal elements corresponding to mediator variables \mathbf{m} are set to zero and the rest to one, i the row index of Y in Φ , j the column index of X in Φ , \mathbf{S} a diagonal matrix with model-implied standard deviations on the diagonals, and Δt the time interval.

50 DirectStd

Value

Returns an object of class ctmedeffect which is a list with the following elements:

```
call Function call.args Function arguments.fun Function used ("DirectStd").output The standardized direct effect.
```

ExpCov

Model-Implied State Covariance Matrix

Description

The function returns the model-implied state covariance matrix for a particular time interval Δt given by

$$\operatorname{vec}\left(\operatorname{Cov}\left(\boldsymbol{\eta}\right)\right) = \left(\mathbf{J} - \boldsymbol{\beta}_{\Delta t} \otimes \boldsymbol{\beta}_{\Delta t}\right)^{-1} \operatorname{vec}\left(\boldsymbol{\Psi}_{\Delta t}\right)$$

where

$$eta_{\Delta t} = \exp\left(\Delta t \mathbf{\Phi}\right),$$
 $oldsymbol{\Psi}_{\Delta t} = \mathbf{\Phi}^{\#} \left(\exp\left(\Delta t \mathbf{\Phi}\right) - \mathbf{J}\right) \operatorname{vec}\left(\mathbf{\Sigma}\right), \quad ext{and}$
 $oldsymbol{\Phi}^{\#} = \left(\mathbf{\Phi} \otimes \mathbf{I}\right) + \left(\mathbf{I} \otimes \mathbf{\Phi}\right).$

Note that I and J are identity matrices.

Usage

```
ExpCov(phi, sigma, delta_t)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names |
|---------|--|
| | pertaining to the variables in the system. |
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| delta_t | Numeric. Time interval (Δt). |

Details

Linear Stochastic Differential Equation Model:

The measurement model is given by

$$\mathbf{y}_{i,t} = oldsymbol{
u} + oldsymbol{\Lambda} oldsymbol{\eta}_{i,t} + oldsymbol{arepsilon}_{i,t}, \quad ext{with} \quad oldsymbol{arepsilon}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, oldsymbol{\Theta}
ight)$$

where $\mathbf{y}_{i,t}$, $\boldsymbol{\eta}_{i,t}$, and $\boldsymbol{\varepsilon}_{i,t}$ are random variables and $\boldsymbol{\nu}$, $\boldsymbol{\Lambda}$, and $\boldsymbol{\Theta}$ are model parameters. $\mathbf{y}_{i,t}$ represents a vector of observed random variables, $\boldsymbol{\eta}_{i,t}$ a vector of latent random variables, and

 $\varepsilon_{i,t}$ a vector of random measurement errors, at time t and individual i. ν denotes a vector of intercepts, Λ a matrix of factor loadings, and Θ the covariance matrix of ε .

An alternative representation of the measurement error is given by

$$\boldsymbol{\varepsilon}_{i,t} = \boldsymbol{\Theta}^{\frac{1}{2}} \mathbf{z}_{i,t}, \quad \text{with} \quad \mathbf{z}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{I}\right)$$

where $\mathbf{z}_{i,t}$ is a vector of independent standard normal random variables and $\left(\Theta^{\frac{1}{2}}\right)\left(\Theta^{\frac{1}{2}}\right)' = \Theta$. The dynamic structure is given by

$$\mathrm{d} oldsymbol{\eta}_{i,t} = \left(oldsymbol{\iota} + oldsymbol{\Phi} oldsymbol{\eta}_{i,t}
ight) \mathrm{d} t + oldsymbol{\Sigma}^{rac{1}{2}} \mathrm{d} \mathbf{W}_{i,t}$$

where ι is a term which is unobserved and constant over time, Φ is the drift matrix which represents the rate of change of the solution in the absence of any random fluctuations, Σ is the matrix of volatility or randomness in the process, and $\mathrm{d} W$ is a Wiener process or Brownian motion, which represents random fluctuations.

Value

Returns a numeric matrix.

ExpMean

Model-Implied State Mean Vector

Description

The function returns the model-implied state mean vector for a particular time interval Δt given by

Mean
$$(\boldsymbol{\eta}) = (\mathbf{I} - \boldsymbol{\beta}_{\Delta t})^{-1} \boldsymbol{\alpha}_{\Delta t}$$

where

$$eta_{\Delta t} = \exp\left(\Delta t \mathbf{\Phi}\right),$$
 $oldsymbol{lpha}_{\Delta t} = \mathbf{\Phi}^{-1} \left(oldsymbol{eta}_{\Delta t} - \mathbf{I}\right) oldsymbol{\iota}.$

Note that **I** is an identity matrix.

Usage

```
ExpMean(phi, iota, delta_t)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ), phi should have row and column names pertaining to the variables in the system. |
|---------|--|
| iota | Numeric vector. An unobserved term that is constant over time (ι). |
| delta_t | Numeric. Time interval (Δt). |

Indirect 55

Indirect

Indirect Effect of X on Y Through M Over a Specific Time Interval

Description

This function computes the indirect effect of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$.

Usage

Indirect(phi, delta_t, from, to, med)

Arguments

| phi | Numeric matrix. The drift matrix (Φ). phi should have row and column names pertaining to the variables in the system. | |
|---------|--|--|
| delta_t | Numeric. Time interval (Δt). | |
| from | Character string. Name of the independent variable X in \mathtt{phi} . | |
| to | Character string. Name of the dependent variable Y in phi. | |
| med | Character vector. Name/s of the mediator variable/s in phi. | |

Details

The indirect effect of the independent variable X on the dependent variable Y relative to some mediator variables \mathbf{m} over a specific time interval Δt is given by

Indirect_{$$\Delta t_{i,j}$$} = exp $(\Delta t \mathbf{\Phi})_{i,j}$ - exp $(\Delta t \mathbf{D_m} \mathbf{\Phi} \mathbf{D_m})_{i,j}$

where Φ denotes the drift matrix, $\mathbf{D_m}$ a matrix where the off diagonal elements are zeros and the diagonal elements are zero for the index/indices of mediator variables \mathbf{m} and one otherwise, i the row index of Y in Φ , j the column index of X in Φ , and Δt the time interval.

Linear Stochastic Differential Equation Model:

The measurement model is given by

$$\mathbf{y}_{i,t} = \mathbf{\nu} + \mathbf{\Lambda} \boldsymbol{\eta}_{i:t} + \boldsymbol{\varepsilon}_{i,t}, \quad ext{with} \quad \boldsymbol{\varepsilon}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{\Theta}\right)$$

where $\mathbf{y}_{i,t}$, $\eta_{i,t}$, and $\varepsilon_{i,t}$ are random variables and $\boldsymbol{\nu}$, $\boldsymbol{\Lambda}$, and $\boldsymbol{\Theta}$ are model parameters. $\mathbf{y}_{i,t}$ represents a vector of observed random variables, $\eta_{i,t}$ a vector of latent random variables, and $\varepsilon_{i,t}$ a vector of random measurement errors, at time t and individual i. $\boldsymbol{\nu}$ denotes a vector of intercepts, $\boldsymbol{\Lambda}$ a matrix of factor loadings, and $\boldsymbol{\Theta}$ the covariance matrix of ε .

An alternative representation of the measurement error is given by

$$\boldsymbol{\varepsilon}_{i,t} = \boldsymbol{\Theta}^{\frac{1}{2}} \mathbf{z}_{i,t}, \quad \text{with} \quad \mathbf{z}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{I}\right)$$

where $\mathbf{z}_{i,t}$ is a vector of independent standard normal random variables and $\left(\mathbf{\Theta}^{\frac{1}{2}}\right)\left(\mathbf{\Theta}^{\frac{1}{2}}\right)' = \mathbf{\Theta}$.

56 Indirect

The dynamic structure is given by

$$\mathrm{d}\boldsymbol{\eta}_{i,t} = \left(\boldsymbol{\iota} + \boldsymbol{\Phi} \boldsymbol{\eta}_{i,t}\right) \mathrm{d}t + \boldsymbol{\Sigma}^{\frac{1}{2}} \mathrm{d}\mathbf{W}_{i,t}$$

where ι is a term which is unobserved and constant over time, Φ is the drift matrix which represents the rate of change of the solution in the absence of any random fluctuations, Σ is the matrix of volatility or randomness in the process, and $\mathrm{d}W$ is a Wiener process or Brownian motion, which represents random fluctuations.

Value

Returns an object of class ctmedeffect which is a list with the following elements:

```
call Function call.args Function arguments.
```

fun Function used ("Indirect").

output The indirect effect.

IndirectCentral

Indirect Effect Centrality

Description

Indirect Effect Centrality

Usage

```
IndirectCentral(phi, delta_t, tol = 0.01)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) , phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| delta_t | Vector of positive numbers. Time interval (Δt) . |
| tol | Numeric. Smallest possible time interval to allow. |

58 IndirectCentral

Details

Indirect effect centrality is the sum of all possible indirect effects between different pairs of variables in which a specific variable serves as the only mediator.

Value

Returns an object of class ctmedmed which is a list with the following elements:

```
call Function call.args Function arguments.fun Function used ("IndirectCentral").output A matrix of indirect effect centrality.
```

IndirectStd

Standardized Indirect Effect of X on Y Through M Over a Specific Time Interval

Description

This function computes the standardized indirect effect of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$ and process noise covariance matrix $\mathbf{\Sigma}$.

Usage

```
IndirectStd(phi, sigma, delta_t, from, to, med)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |

60 IndirectStd

Details

The standardized indirect effect of the independent variable X on the dependent variable Y relative to some mediator variables \mathbf{m} over a specific time interval Δt is given by

$$\operatorname{Indirect}_{\Delta t_{i,j}}^* = \operatorname{Total}_{\Delta t}^* - \operatorname{Direct}_{\Delta t}^*$$

where $\operatorname{Total}_{\Delta t}^*$ and $\operatorname{Direct}_{\Delta t}^*$ are standardized total and direct effects for time interval Δt .

Value

Returns an object of class ctmedeffect which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("IndirectStd").

output The standardized indirect effect.

MCBeta

Monte Carlo Sampling Distribution for the Elements of the Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a Monte Carlo method sampling distribution for the elements of the matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix Φ .

Usage

```
MCBeta(
   phi,
   vcov_phi_vec,
   delta_t,
   R,
   test_phi = TRUE,
   ncores = NULL,
   seed = NULL,
   tol = 0.01
)
```

Arguments

phi

Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system.

62 MCBeta

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of vec (Φ) .

delta_t Numeric. Time interval (Δt).

R Positive integer. Number of replications.

test_phi Logical. If test_phi = TRUE, the function tests the stability of the generated

drift matrix Φ . If the test returns FALSE, the function generates a new drift

matrix Φ and runs the test recursively until the test returns TRUE.

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when number of replications R is a large value.

seed Random seed.

tol Numeric. Smallest possible time interval to allow.

Details

See Total().

Monte Carlo Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCBeta").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est Estimated elements of the matrix of lagged coefficients.

thetahatstar A matrix of Monte Carlo elements of the matrix of lagged coefficients.

Monte Carlo Sampling Distribution for the Elements of the Standardized Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals MCBetaStd 65

Description

This function generates a Monte Carlo method sampling distribution for the elements of the standardized matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix Φ and process noise covariance matrix Σ .

Usage

```
MCBetaStd(
  phi,
  sigma,
  vcov_theta,
  delta_t,
  R,
  test_phi = TRUE,
  ncores = NULL,
  seed = NULL,
  tol = 0.01
)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ). phi should have row and column names pertaining to the variables in the system. |
|------------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| vcov_theta | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\mathbf{\Phi}\right)$ and $\operatorname{vech}\left(\mathbf{\Sigma}\right)$ |
| delta_t | Numeric. Time interval (Δt). |
| R | Positive integer. Number of replications. |
| test_phi | Logical. If test_phi = TRUE, the function tests the stability of the generated drift matrix Φ . If the test returns FALSE, the function generates a new drift matrix Φ and runs the test recursively until the test returns TRUE. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| seed | Random seed. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd().

Monte Carlo Method:

Let θ be a vector that combines $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise and $\operatorname{vech}(\Sigma)$, that is, the unique elements of the Σ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be a vector that combines $\operatorname{vec}(\hat{\Phi})$ and $\operatorname{vech}(\hat{\Sigma})$. Based on the

asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCBetaStd").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est Estimated elements of the standardized matrix of lagged coefficients.

thetahatstar A matrix of Monte Carlo elements of the standardized matrix of lagged coefficients.

MCIndirectCentral 69

| MCIndirectCentral | Monte Carlo Sampling Distribution of Indirect Effect Centrality Over |
|-------------------|--|
| | a Specific Time Interval or a Range of Time Intervals |

Description

This function generates a Monte Carlo method sampling distribution of the indirect effect centrality at a particular time interval Δt using the first-order stochastic differential equation model drift matrix Φ .

Usage

```
MCIndirectCentral(
  phi,
  vcov_phi_vec,
  delta_t,
  R,
  test_phi = TRUE,
  ncores = NULL,
  seed = NULL,
  tol = 0.01
)
```

Arguments

| • | natrix. The drift matrix (Φ) , phi should have row and column names to the variables in the system. |
|------------------------|---|
| vcov_phi_vec Numeric n | natrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\mathbf{\Phi}\right)$. |
| delta_t Numeric. | Time interval (Δt) . |
| R Positive in | teger. Number of replications. |
| drift matri | If test_phi = TRUE, the function tests the stability of the generated $\mathbf{x} \mathbf{\Phi}$. If the test returns FALSE, the function generates a new drift and runs the test recursively until the test returns TRUE. |
| | steger. Number of cores to use. If ncores = NULL, use a single core. using multiple cores when number of replications R is a large value. |
| seed Random se | eed. |
| | |

Details

See IndirectCentral() for more details.

Monte Carlo Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCIndirectCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est A vector of indirect effect centrality.

thetahatstar A matrix of Monte Carlo indirect effect centrality.

MCMed

Monte Carlo Sampling Distribution of Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a Monte Carlo method sampling distribution of the total, direct and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix $\mathbf{\Phi}$.

Usage

```
MCMed(
   phi,
   vcov_phi_vec,
   delta_t,
   from,
   to,
   med,
   R,
```

MCMed 73

```
test_phi = TRUE,
ncores = NULL,
seed = NULL,
tol = 0.01
)
```

Arguments

phi Numeric matrix. The drift matrix (Φ), phi should have row and column names

pertaining to the variables in the system.

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$.

delta_t Numeric. Time interval (Δt).

from Character string. Name of the independent variable X in phi. to Character string. Name of the dependent variable Y in phi. med Character vector. Name/s of the mediator variable/s in phi.

R Positive integer. Number of replications.

test_phi Logical. If test_phi = TRUE, the function tests the stability of the generated

drift matrix Φ . If the test returns FALSE, the function generates a new drift

matrix Φ and runs the test recursively until the test returns TRUE.

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when number of replications R is a large value.

seed Random seed.

tol Numeric. Smallest possible time interval to allow.

Details

See Total(), Direct(), and Indirect() for more details.

Monte Carlo Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{\boldsymbol{\theta}}^* \sim \mathcal{N}\left(\hat{\boldsymbol{\theta}}, \hat{\mathbb{V}}\left(\hat{\boldsymbol{\theta}}\right)\right).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

74 MCMed

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCMed").

output A list with length of length(delta_t).

Each element in the output list has the following elements:

est A vector of total, direct, and indirect effects.

thetahatstar A matrix of Monte Carlo total, direct, and indirect effects.

MCMedStd

Monte Carlo Sampling Distribution of Standardized Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a Monte Carlo method sampling distribution of the standardized total, direct and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix $\mathbf{\Phi}$ and process noise covariance matrix $\mathbf{\Sigma}$.

Usage

```
MCMedStd(
    phi,
    sigma,
    vcov_theta,
    delta_t,
    from,
    to,
    med,
    R,
    test_phi = TRUE,
    ncores = NULL,
    seed = NULL,
    tol = 0.01
)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ). phi should have row and column names pertaining to the variables in the system. |
|------------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| vcov_theta | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$ and $\operatorname{vech}\left(\Sigma\right)$ |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |

| to | Character string. Name of the dependent variable Y in phi. |
|----------|---|
| med | Character vector. Name/s of the mediator variable/s in phi. |
| R | Positive integer. Number of replications. |
| test_phi | Logical. If test_phi = TRUE, the function tests the stability of the generated drift matrix Φ . If the test returns FALSE, the function generates a new drift matrix Φ and runs the test recursively until the test returns TRUE. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| seed | Random seed. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd(), DirectStd(), and IndirectStd() for more details.

Monte Carlo Method:

Let θ be a vector that combines $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise and $\operatorname{vech}(\Sigma)$, that is, the unique elements of the Σ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be a vector that combines $\operatorname{vec}(\hat{\Phi})$ and $\operatorname{vech}(\hat{\Sigma})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCMedStd").

output A list with length of length(delta_t).

Each element in the output list has the following elements:

est A vector of standardized total, direct, and indirect effects.

thetahatstar A matrix of Monte Carlo standardized total, direct, and indirect effects.

Generate Random Drift Matrices Using the Monte Carlo Method

Description

This function generates random drift matrices Φ using the Monte Carlo method.

Usage

```
MCPhi(phi, vcov_phi_vec, R, test_phi = TRUE, ncores = NULL, seed = NULL)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ). phi should have row and column names pertaining to the variables in the system. |
|--------------|---|
| vcov_phi_vec | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\Phi\right)$. |
| R | Positive integer. Number of replications. |
| test_phi | Logical. If test_phi = TRUE, the function tests the stability of the generated drift matrix Φ . If the test returns FALSE, the function generates a new drift matrix Φ and runs the test recursively until the test returns TRUE. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| seed | Random seed. |

MCPhi 81

Details

Monte Carlo Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCPhi").

output A list simulated drift matrices.

MCPhiSigma

Generate Random Drift Matrices and Process Noise Covariance Matrices Using the Monte Carlo Method

Description

This function generates random drift matrices Φ and process noise covariabces matrices Σ using the Monte Carlo method.

Usage

```
MCPhiSigma(
  phi,
  sigma,
  vcov_theta,
  R,
  test_phi = TRUE,
  ncores = NULL,
  seed = NULL
)
```

Arguments

Numeric matrix. The drift matrix (Φ). phi should have row and column names pertaining to the variables in the system.

sigma Numeric matrix. The process noise covariance matrix (Σ) .

MCPhiSigma 83

| vcov_theta | Numeric matrix. The sampling variance-covariance matrix of $\operatorname{vec}\left(\mathbf{\Phi}\right)$ and $\operatorname{vech}\left(\mathbf{\Sigma}\right)$ |
|------------|---|
| R | Positive integer. Number of replications. |
| test_phi | Logical. If test_phi = TRUE, the function tests the stability of the generated drift matrix Φ . If the test returns FALSE, the function generates a new drift matrix Φ and runs the test recursively until the test returns TRUE. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| seed | Random seed. |

Details

Monte Carlo Method:

Let θ be a vector that combines $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise and $\operatorname{vech}(\Sigma)$, that is, the unique elements of the Σ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be a vector that combines $\operatorname{vec}(\hat{\Phi})$ and $\operatorname{vech}(\hat{\Sigma})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCPhiSigma").

output A list simulated drift matrices.

MCTotalCentral

Monte Carlo Sampling Distribution of Total Effect Centrality Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a Monte Carlo method sampling distribution of the total effect centrality at a particular time interval Δt using the first-order stochastic differential equation model drift matrix Φ .

Usage

```
MCTotalCentral(
  phi,
  vcov_phi_vec,
  delta_t,
  R,
  test_phi = TRUE,
  ncores = NULL,
  seed = NULL,
  tol = 0.01
)
```

MCTotalCentral 85

Arguments

phi Numeric matrix. The drift matrix (Φ), phi should have row and column names

pertaining to the variables in the system.

vcov_phi_vec Numeric matrix. The sampling variance-covariance matrix of vec (Φ) .

delta_t Numeric. Time interval (Δt).

R Positive integer. Number of replications.

test_phi Logical. If test_phi = TRUE, the function tests the stability of the generated

drift matrix Φ . If the test returns FALSE, the function generates a new drift

matrix Φ and runs the test recursively until the test returns TRUE.

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when number of replications R is a large value.

seed Random seed.

tol Numeric. Smallest possible time interval to allow.

Details

See TotalCentral() for more details.

Monte Carlo Method:

Let θ be $\operatorname{vec}(\Phi)$, that is, the elements of the Φ matrix in vector form sorted column-wise. Let $\hat{\theta}$ be $\operatorname{vec}(\hat{\Phi})$. Based on the asymptotic properties of maximum likelihood estimators, we can assume that estimators are normally distributed around the population parameters.

$$\hat{oldsymbol{ heta}} \sim \mathcal{N}\left(oldsymbol{ heta}, \mathbb{V}\left(\hat{oldsymbol{ heta}}
ight)
ight)$$

Using this distributional assumption, a sampling distribution of $\hat{\theta}$ which we refer to as $\hat{\theta}^*$ can be generated by replacing the population parameters with sample estimates, that is,

$$\hat{oldsymbol{ heta}}^* \sim \mathcal{N}\left(\hat{oldsymbol{ heta}}, \hat{\mathbb{V}}\left(\hat{oldsymbol{ heta}}
ight)
ight).$$

Let $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$ be a parameter that is a function of the estimated parameters. A sampling distribution of $\mathbf{g}\left(\hat{\boldsymbol{\theta}}\right)$, which we refer to as $\mathbf{g}\left(\hat{\boldsymbol{\theta}}^*\right)$, can be generated by using the simulated estimates to calculate \mathbf{g} . The standard deviations of the simulated estimates are the standard errors. Percentiles corresponding to $100\left(1-\alpha\right)\%$ are the confidence intervals.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("MCTotalCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est A vector of total effect centrality.

thetahatstar A matrix of Monte Carlo total effect centrality.

Med

Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the total, direct, and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of

88 Med

time intervals using the first-order stochastic differential equation model's drift matrix Φ .

Usage

```
Med(phi, delta_t, from, to, med, tol = 0.01)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| delta_t | Vector of positive numbers. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See Total(), Direct(), and Indirect() for more details.

Linear Stochastic Differential Equation Model:

The measurement model is given by

$$\mathbf{y}_{i,t} = \boldsymbol{\nu} + \boldsymbol{\Lambda} \boldsymbol{\eta}_{i,t} + \boldsymbol{arepsilon}_{i,t}, \quad ext{with} \quad \boldsymbol{arepsilon}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, oldsymbol{\Theta}
ight)$$

where $\mathbf{y}_{i,t}$, $\boldsymbol{\eta}_{i,t}$, and $\boldsymbol{\varepsilon}_{i,t}$ are random variables and $\boldsymbol{\nu}$, $\boldsymbol{\Lambda}$, and $\boldsymbol{\Theta}$ are model parameters. $\mathbf{y}_{i,t}$ represents a vector of observed random variables, $\boldsymbol{\eta}_{i,t}$ a vector of latent random variables, and $\boldsymbol{\varepsilon}_{i,t}$ a vector of random measurement errors, at time t and individual i. $\boldsymbol{\nu}$ denotes a vector of intercepts, $\boldsymbol{\Lambda}$ a matrix of factor loadings, and $\boldsymbol{\Theta}$ the covariance matrix of $\boldsymbol{\varepsilon}$.

An alternative representation of the measurement error is given by

$$\boldsymbol{\varepsilon}_{i,t} = \boldsymbol{\Theta}^{\frac{1}{2}} \mathbf{z}_{i,t}, \quad \text{with} \quad \mathbf{z}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{I}\right)$$

where $\mathbf{z}_{i,t}$ is a vector of independent standard normal random variables and $\left(\Theta^{\frac{1}{2}}\right)\left(\Theta^{\frac{1}{2}}\right)' = \Theta$. The dynamic structure is given by

$$\mathrm{d}oldsymbol{\eta}_{i,t} = \left(oldsymbol{\iota} + oldsymbol{\Phi}oldsymbol{\eta}_{i,t}
ight)\mathrm{d}t + oldsymbol{\Sigma}^{rac{1}{2}}\mathrm{d}\mathbf{W}_{i,t}$$

where ι is a term which is unobserved and constant over time, Φ is the drift matrix which represents the rate of change of the solution in the absence of any random fluctuations, Σ is the matrix of volatility or randomness in the process, and $\mathrm{d} W$ is a Wiener process or Brownian motion, which represents random fluctuations.

Value

Returns an object of class ctmedmed which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("Med").

output A matrix of total, direct, and indirect effects.

Med 89

MedStd

Standardized Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function computes the standardized total, direct, and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model's drift matrix $\mathbf{\Phi}$ and process noise covariance matrix $\mathbf{\Sigma}$.

Usage

```
MedStd(phi, sigma, delta_t, from, to, med, tol = 0.01)
```

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . |
| delta_t | Numeric. Time interval (Δt). |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalStd(), DirectStd(), and IndirectStd() for more details.

Plot Method for an Object of Class ctmedboot

Description

Plot Method for an Object of Class ctmedboot

Usage

```
## S3 method for class 'ctmedboot'
plot(x, alpha = 0.05, col = NULL, type = "pc", ...)
```

plot.ctmedboot 93

Arguments

| x | Object of class ctmedboot. |
|-------|---|
| alpha | Numeric. Significance level |
| col | Character vector. Optional argument. Character vector of colors. |
| type | Charater string. Confidence interval type, that is, type = "pc" for percentile; type = "bc" for bias corrected. |
| | Additional arguments. |

Value

Displays plots of point estimates and confidence intervals.

plot.ctmeddelta

Plot Method for an Object of Class ctmeddelta

Description

Plot Method for an Object of Class ctmeddelta

Usage

```
## S3 method for class 'ctmeddelta'
plot(x, alpha = 0.05, col = NULL, ...)
```

Arguments

| X | Object of class ctmeddelta. |
|-------|--|
| alpha | Numeric. Significance level |
| col | Character vector. Optional argument. Character vector of colors. |
| | Additional arguments. |

Value

Displays plots of point estimates and confidence intervals.

)
plot(med)
```

plot.ctmedtraj

Plot Method for an Object of Class ctmedtraj

Description

Plot Method for an Object of Class ctmedtraj

Usage

```
## S3 method for class 'ctmedtraj'
plot(x, legend_pos = "topright", total = TRUE, ...)
```

100 PosteriorBeta

Arguments

| X | Object of class ctmedtraj. |
|------------|---|
| legend_pos | Character vector. Optional argument. Legend position. |
| total | Logical. If total = TRUE, include the total effect trajectory. If total = FALSE, exclude the total effect trajectory. |
| | Additional arguments. |

Value

Displays trajectory plots of the effects.

Author(s)

Ivan Jacob Agaloos Pesigan

Examples

```
phi <- matrix(</pre>
  data = c(
    -0.357, 0.771, -0.450,
    0.0, -0.511, 0.729,
    0, 0, -0.693
  ),
  nrow = 3
)
colnames(phi) <- rownames(phi) <- c("x", "m", "y")</pre>
traj <- Trajectory(</pre>
  mu0 = c(3, 3, -3),
  time = 150,
  phi = phi,
  med = "m"
)
plot(traj)
```

PosteriorBeta

Posterior Sampling Distribution for the Elements of the Matrix of Lagged Coefficients Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a posterior sampling distribution for the elements of the matrix of lagged coefficients β over a specific time interval Δt or a range of time intervals using the first-order stochastic differential equation model drift matrix Φ .

PosteriorBeta 101

Usage

```
PosteriorBeta(phi, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

phi Numeric matrix. The drift matrix (Φ), phi should have row and column names

pertaining to the variables in the system.

delta_t Numeric. Time interval (Δt).

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core.

Consider using multiple cores when number of replications R is a large value.

tol Numeric. Smallest possible time interval to allow.

Details

See Total().

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("PosteriorBeta").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est A vector of total, direct, and indirect effects.

thetahatstar A matrix of Monte Carlo total, direct, and indirect effects.

PosteriorIndirectCentral

Posterior Distribution of the Indirect Effect Centrality Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a posterior distribution of the indirect effect centrality over a specific time interval Δt or a range of time intervals using the posterior distribution of the first-order stochastic differential equation model drift matrix Φ .

Usage

```
PosteriorIndirectCentral(phi, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a sample from the posterior |
|-----|---|
| | distribution of the drift matrix (Φ). Each matrix should have row and column |
| | names pertaining to the variables in the system. |

delta_t Numeric. Time interval (Δt) .

104 PosteriorIndirectCentral

ncores Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value.

tol Numeric. Smallest possible time interval to allow.

Details

See TotalCentral() for more details.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("PosteriorIndirectCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est Mean of the posterior distribution of the total, direct, and indirect effects.

thetahatstar Posterior distribution of the total, direct, and indirect effects.

106 PosteriorMed

PosteriorMed

Posterior Distribution of Total, Direct, and Indirect Effects of X on Y Through M Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a posterior distribution of the total, direct and indirect effects of the independent variable X on the dependent variable Y through mediator variables \mathbf{m} over a specific time interval Δt or a range of time intervals using the posterior distribution of the first-order stochastic differential equation model drift matrix $\mathbf{\Phi}$.

Usage

```
PosteriorMed(phi, delta_t, from, to, med, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a sample from the posterior distribution of the drift matrix (Φ). Each matrix should have row and column names pertaining to the variables in the system. |
|---------|--|
| delta_t | Numeric. Time interval (Δt) . |
| from | Character string. Name of the independent variable X in phi. |
| to | Character string. Name of the dependent variable Y in phi. |
| med | Character vector. Name/s of the mediator variable/s in phi. |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

PosteriorMed 107

Details

See Total(), Direct(), and Indirect() for more details.

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("PosteriorMed").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est Mean of the posterior distribution of the total, direct, and indirect effects.

thetahatstar Posterior distribution of the total, direct, and indirect effects.

PosteriorTotalCentral 109

Posterior Total Central $\,$ Posterior Distribution of the Total Effect Centrality Over a Specific Time Interval or a Range of Time Intervals

Description

This function generates a posterior distribution of the total effect centrality over a specific time interval Δt or a range of time intervals using the posterior distribution of the first-order stochastic differential equation model drift matrix Φ .

Usage

```
PosteriorTotalCentral(phi, delta_t, ncores = NULL, tol = 0.01)
```

Arguments

| phi | List of numeric matrices. Each element of the list is a sample from the posterior distribution of the drift matrix (Φ). Each matrix should have row and column names pertaining to the variables in the system. |
|---------|--|
| delta_t | Numeric. Time interval (Δt) . |
| ncores | Positive integer. Number of cores to use. If ncores = NULL, use a single core. Consider using multiple cores when number of replications R is a large value. |
| tol | Numeric. Smallest possible time interval to allow. |

Details

See TotalCentral() for more details.

110 PosteriorTotalCentral

Value

Returns an object of class ctmedmc which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("PosteriorTotalCentral").

output A list the length of which is equal to the length of delta_t.

Each element in the output list has the following elements:

est Mean of the posterior distribution of the total, direct, and indirect effects.

thetahatstar Posterior distribution of the total, direct, and indirect effects.

Print Method for Object of Class ctmedboot

Description

Print Method for Object of Class ctmedboot

Usage

```
## S3 method for class 'ctmedboot'
print(x, alpha = 0.05, digits = 4, type = "pc", ...)
```

Arguments

x an object of class ctmedboot. alpha Numeric vector. Significance level α . digits Integer indicating the number of decimal places to display. type Charater string. Confidence interval type, that is, type = "pc" for percentile; type = "bc" for bias corrected. ... further arguments.

Value

Prints a list of matrices of time intervals, estimates, standard errors, number of bootstrap replications, and confidence intervals.

## S3 method for class 'ctmedtraj'
print(x, ...)
```

Arguments

```
x an object of class ctmedtraj.... further arguments.
```

Value

Prints a data frame of simulated data.

Author(s)

Ivan Jacob Agaloos Pesigan

```
phi <- matrix(
  data = c(
    -0.357, 0.771, -0.450,
    0.0, -0.511, 0.729,
    0, 0, -0.693
  ),
  nrow = 3
)</pre>
```

```
colnames(phi) <- rownames(phi) <- c("x", "m", "y")

traj <- Trajectory(
  mu0 = c(3, 3, -3),
  time = 150,
  phi = phi,
  med = "m"
)

print(traj)</pre>
```

summary.ctmedboot

Summary Method for an Object of Class ctmedboot

Description

Summary Method for an Object of Class ctmedboot

Usage

```
## S3 method for class 'ctmedboot'
summary(object, alpha = 0.05, type = "pc", ...)
```

Arguments

object Object of class ctmedboot.
 alpha Numeric vector. Significance level α.
 type Charater string. Confidence interval type, that is, type = "pc" for percentile; type = "bc" for bias corrected.
 additional arguments.

Value

Returns a data frame of effects, time intervals, estimates, standard errors, number of bootstrap replications, and confidence intervals.

Author(s)

Ivan Jacob Agaloos Pesigan

Total

Total Effect Matrix Over a Specific Time Interval

Description

This function computes the total effects matrix over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix Φ .

Usage

```
Total(phi, delta_t)
```

Arguments

Numeric matrix. The drift matrix (Φ) , phi should have row and column names pertaining to the variables in the system.

delta_t Numeric. Time interval (Δt).

Total 133

Details

The total effect matrix over a specific time interval Δt is given by

$$Total_{\Delta t} = \exp(\Delta t \mathbf{\Phi})$$

where Φ denotes the drift matrix, and Δt the time interval.

Linear Stochastic Differential Equation Model:

The measurement model is given by

$$\mathbf{y}_{i,t} = \mathbf{\nu} + \mathbf{\Lambda} \boldsymbol{\eta}_{i,t} + \boldsymbol{arepsilon}_{i,t}, \quad ext{with} \quad \boldsymbol{arepsilon}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{\Theta}
ight)$$

where $\mathbf{y}_{i,t}$, $\boldsymbol{\eta}_{i,t}$, and $\boldsymbol{\varepsilon}_{i,t}$ are random variables and $\boldsymbol{\nu}$, $\boldsymbol{\Lambda}$, and $\boldsymbol{\Theta}$ are model parameters. $\mathbf{y}_{i,t}$ represents a vector of observed random variables, $\boldsymbol{\eta}_{i,t}$ a vector of latent random variables, and $\boldsymbol{\varepsilon}_{i,t}$ a vector of random measurement errors, at time t and individual i. $\boldsymbol{\nu}$ denotes a vector of intercepts, $\boldsymbol{\Lambda}$ a matrix of factor loadings, and $\boldsymbol{\Theta}$ the covariance matrix of $\boldsymbol{\varepsilon}$.

An alternative representation of the measurement error is given by

$$\boldsymbol{\varepsilon}_{i,t} = \boldsymbol{\Theta}^{\frac{1}{2}} \mathbf{z}_{i,t}, \quad \text{with} \quad \mathbf{z}_{i,t} \sim \mathcal{N}\left(\mathbf{0}, \mathbf{I}\right)$$

where $\mathbf{z}_{i,t}$ is a vector of independent standard normal random variables and $\left(\Theta^{\frac{1}{2}}\right)\left(\Theta^{\frac{1}{2}}\right)' = \Theta$. The dynamic structure is given by

$$\mathrm{d}\boldsymbol{\eta}_{i,t} = \left(\boldsymbol{\iota} + \boldsymbol{\Phi}\boldsymbol{\eta}_{i,t}\right) \mathrm{d}t + \boldsymbol{\Sigma}^{\frac{1}{2}} \mathrm{d}\mathbf{W}_{i,t}$$

where ι is a term which is unobserved and constant over time, Φ is the drift matrix which represents the rate of change of the solution in the absence of any random fluctuations, Σ is the matrix of volatility or randomness in the process, and $\mathrm{d}W$ is a Wiener process or Brownian motion, which represents random fluctuations.

Value

Returns an object of class ctmedeffect which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("Total").

output The matrix of total effects.

TotalCentral

Total Effect Centrality

Description

Total Effect Centrality

Usage

```
TotalCentral(phi, delta_t, tol = 0.01)
```

TotalCentral 135

Arguments

| phi | Numeric matrix. The drift matrix (Φ) , phi should have row and column names pertaining to the variables in the system. |
|---------|---|
| delta_t | Vector of positive numbers. Time interval (Δt) . |
| tol | Numeric. Smallest possible time interval to allow. |

Details

The total effect centrality of a variable is the sum of the total effects of a variable on all other variables at a particular time interval.

Value

Returns an object of class ctmedmed which is a list with the following elements:

```
call Function call.args Function arguments.fun Function used ("TotalCentral").output A matrix of total effect centrality.
```

TotalStd

Standardized Total Effect Matrix Over a Specific Time Interval

Description

This function computes the standardized total effects matrix over a specific time interval Δt using the first-order stochastic differential equation model's drift matrix Φ and process noise covariance matrix Σ .

Usage

```
TotalStd(phi, sigma, delta_t)
```

TotalStd 137

Arguments

| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column natrix | |
|---------|---|--|
| | pertaining to the variables in the system. | |
| sigma | Numeric matrix. The process noise covariance matrix (Σ) . | |
| delta_t | Numeric. Time interval (Δt). | |

Details

The standardized total effect matrix over a specific time interval Δt is given by

$$\operatorname{Total}_{\Delta t}^{*} = \mathbf{S} \left(\exp \left(\Delta t \mathbf{\Phi} \right) \right) \mathbf{S}^{-1}$$

where Φ denotes the drift matrix, ${\bf S}$ a diagonal matrix with model-implied standard deviations on the diagonals and Δt the time interval.

Value

Returns an object of class ctmedeffect which is a list with the following elements:

call Function call.

args Function arguments.

fun Function used ("TotalStd").

output The standardized matrix of total effects.

Trajectory

Simulate Trajectories of Variables

Description

This function simulates trajectories of variables without measurement error or process noise. Total corresponds to the total effect and Direct corresponds to the portion of the total effect where the indirect effect is removed.

Usage

```
Trajectory(mu0, time, phi, med)
```

Arguments

| mu0 | Numeric vector. Initial values of the variables. |
|------|---|
| time | Positive integer. Number of time points. |
| phi | Numeric matrix. The drift matrix (Φ) . phi should have row and column names pertaining to the variables in the system. |
| med | Character vector. Name/s of the mediator variable/s in phi. |

Trajectory 139

Value

Returns an object of class ctmedtraj which is a list with the following elements:

```
call Function call.args Function arguments.fun Function used ("Trajectory").output A data frame of simulated data.
```
